A talk box is a device which allows you to adjust your voice from a microphone or a recording to whatever range you choose, add reverb or echo, or to get an unnatural buzz or squeak if you don't like the sound of your voice. A talk box consists of a built-in speaker and a microphone, the acoustic properties of which

are then modified to produce the desired results. A talk box is an example of an all-pass filter. The quality of the audio results of a built-in speaker and a microphone depends on the specification of the properties (attenuation, phase shift etc.) of the filter circuit and the circuit that mixes the speaker's output signal with the microphone's input signal. The sound produced by a talk box is not always the same as the original sound of the mic or the speaker, so the sound is not the best possible sound you could hear through speakers, but you can manipulate the sound to a degree to produce interesting results. For instance, turning the settings of the vocal processing plug-ins up will exaggerate any vocal effect, while decreasing the settings will attenuate your voice. The sensitivity of the controls will determine how accurate the sound of your voice will sound, and how much your voice will be changed by the effects. Most talk boxes have knobs to adjust the level and frequency of the voice to be delivered. The volume setting of the talk box usually affects the level of the voice to be altered, and the frequency setting controls the
